

CMR API Spec

Overview

This document outlines the requirements for the development and delivery of RESTful APIs that AcreIQ customers can call to retrieve their CMR data. The API will return json structured data in response to HTTP GET requests with appropriate authentication and versioning capability.

API Specifications

3 APIs are being requested, one primary API which will return the CMR data and 2 helper APIs which users can optionally call to get a list of reports for a project and get the project number for a given project name.

1. Get CMR Report Data for a given project.

Users should be able to call a GET REST API with a project name or a project number. They can optionally pass a report number, if no report number is passed then the user gets the latest report.

- API Call

- i. By Project Number/Project Name without a report number

GET <https://api.acreiq.com/cmldata/v1/project?projectNumber=12345>

GET <https://api.acreiq.com/cmldata/v1/project?projectName=Fordham%20Apartments>

This will return the data for the last report published for this project.

- ii. By Project Number/Project Name and report number

GET </cmldata/v1/project?projectNumber=12345&reportNumber=3>

GET </cmldata/v1/project?projectName=Fordham%20Apartments&reportNumber=3>

This will return the data for the specified report for this project.

- API Response Fields

This will return all the fields that get published in the report pdf.

2. Helper API: Get Report List

Returns list of report number and its details for a given project

- API Call

GET </getReportList/v1/project?projectNumber=12345>

GET /getReportList/v1/project? projectName=Fordham%20Apartments

- API Response Fields

- Project Number
- Project Name
- Report Type – CMR (in case we add other report types in the future)
- Report Number
- Report Status
- Report Date
- Draw#
- PayApp#

3. Helper API: Get Project Number

Returns project number for a given project name.

- API Call

<https://api.acreiq.com/getProjectNumber/v1/projectName/{projectName}>

- Calling Parameters

- Project Name (required)

- API Response Fields

- ProjectName
- Project Number
- Project Type

4. Error Handling:

API should have graceful error handling, with helpful descriptions in case of client-side errors (e.g. 400 or 404) or server-side errors e.g. 503/504.

Example if an unknown project or report number was passed it should return a helpful 404 error like “Project Name Alpha not found” , or “Report Number 5 not found for Project Alpha”

5. API Security

- Authentication: API Key or OAuth 2.0 (to be finalized)
- HTTPS required for all requests
- Rate limiting to ensure we don't have bad callers that strain the system or cause the system to go down.
